

C.23.4 Define the template `Map_Key<T1, T2>` class with two private members of type `T1` and `T2`. Add appropriate functions in the class so that the following program works.

```
template <typename T1, typename T2> class Map_Key
{
private:
    T1 key;
    T2 val;
public:
    ??? check(???); /* Define the check() which takes as parameter a value
(e.g., k) and checks if the value of the key is the same as k. */
    ??? get(???); /* Define the get() so that it returns the val. */
    // Add any other function you think is needed.
};

int main()
{
    Map_Key<string, int> mk_1("One", 1), mk_2("Two", 2);
    Map_Key<string, int> mk_3 = mk_1 + mk_2;
    /* Declare a vector (e.g., v) of type Map_Key and store mk_1, mk_2,
and mk_3 in it. Then, read a string and check if it is stored in v. If it is,
the program should display the value of val. For example, if the user enters
One, the program should display 1. */
    ...
}
```
