Practice Question

Consider the following programs:

- `LinkedList.cpp` – implements a generic linked list and initializes several linked lists based on primitive datatypes.
- `LinkedList2.cpp` – uses ‘class’ in place of ‘struct’ and initializes a linked list of strings.
- `LinkedList3.cpp` – initializes a linked list of employees.

Write a function ‘sort’ in the linked list class which sorts its data type in ascending order.

Note that the sort function will work correctly for the primitive and string data types. However, you have to overload the “>”, “<” and “==” operators for the Employee class for the sorting to work. For the employee class test sorting using both names and id numbers.
